

Thomas Bley

From a monolith to a microservice shop architecture

Backend

Bringmeister.de
Partner von 

code.talks

About me

- Senior PHP Developer
- Linux, PHP, MySQL since 2001
- studied at TU München
- working for Bringmeister in Berlin

The Monolith

- Magento 1 Enterprise: support was discontinued by Adobe, license costs
 - Large codebase with **1.8 mloc***, developed over 10y years by 130 developers:
 - high complexity, strong coupling, multiple API layers
 - unused / unknown / bad code, hard to maintain, bugs
 - security issues, not designed for GDPR
 - many frameworks: Magento Varien, Zend Framework 1, Symfony 2, Laravel 5, ReactPHP, node.js, no Composer
 - Performance issues:
 - add product to cart 400 queries, **order placement 3.2k queries** (5 transactions)
 - slow queries, deadlocks, memory limit issues
 - Admin login >60s, single order search in Admin 15s
 - database designed by Entity-attribute-value model (big joins)
 - aggregation tables filled synchronously
- **difficult to scale the business**

* excl. frameworks, libraries

The Monolith #2

- Tests:
 - **coverage <10%**, require 7 GB database dump
 - many tests broken, only run locally, CI only used for deployment
 - mostly manual testing
- Productivity:
 - **slow development** of new features
 - analyzing production issues very complex
 - updates only applied manually
- Multiple sources for product data, mostly not in sync:
 - Database
 - Solr, Algolia
- Small team: 5 developers

Developers not happy, Management not happy, Customers not happy with the shop

How does the monolith look like?

How complex is it?

Maintainability / complexity

Each file is symbolized by a circle. Size of the circle represents the Cyclomatic complexity. Color of the circle represents the Maintainability Index.

Large red circles will be probably hard to maintain.

Varien_Db_Adapter_Pdo_Mysql
Cyclomatic Complexity : 411
Maintainability Index: 41.01

CI/CD, Operations

Was wir **haben**

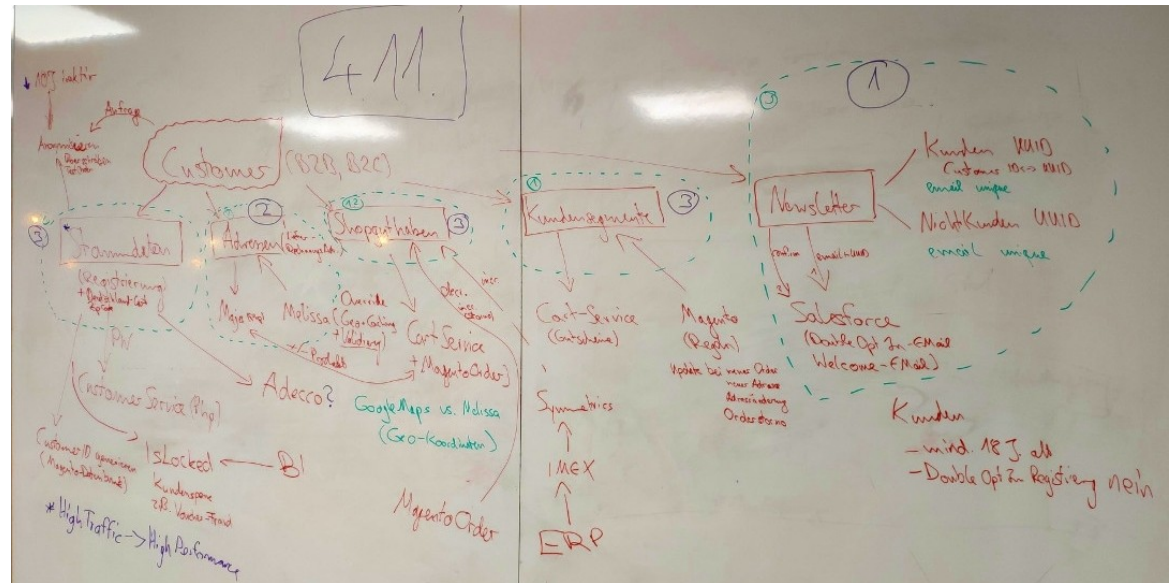

Was wir **brauchen**

Why microservices?

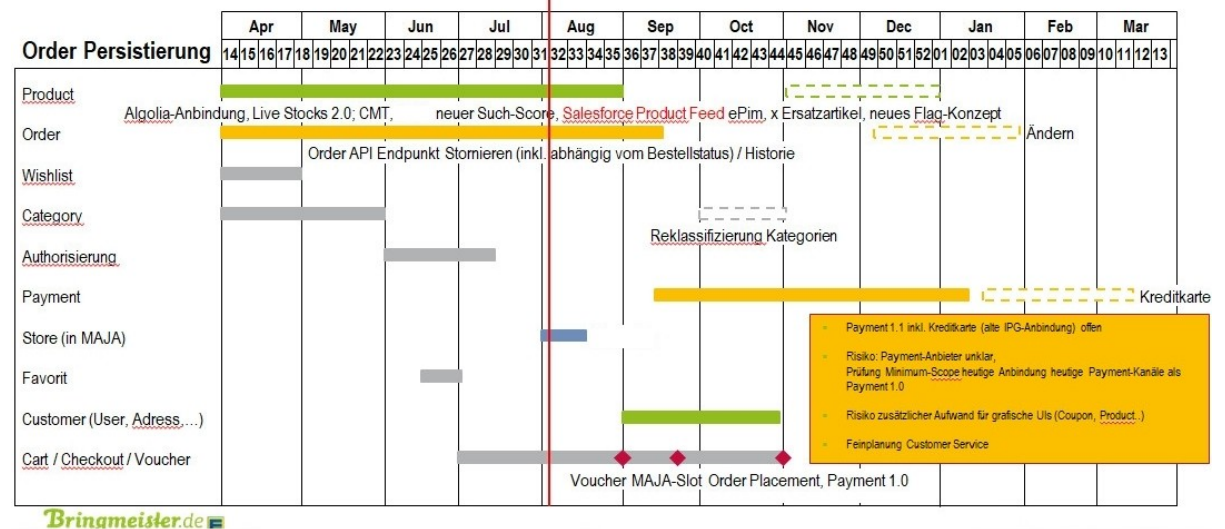

- Smaller code base to work on
 - easier to develop, easier to change, easier to maintain
 - less complexity, focus on problem solving
- More options for databases and programming languages
- Easier to split work on multiple teams
- Hard system boundary with standard communication between services
- Limit impact of bugs and failures
- Isolation of data
 - less complexity in data storage
 - more complexity to join data

Explaining the project to developers

Explaining the project to management

Meilensteinplan – Backend - BestCase

Define the future architecture

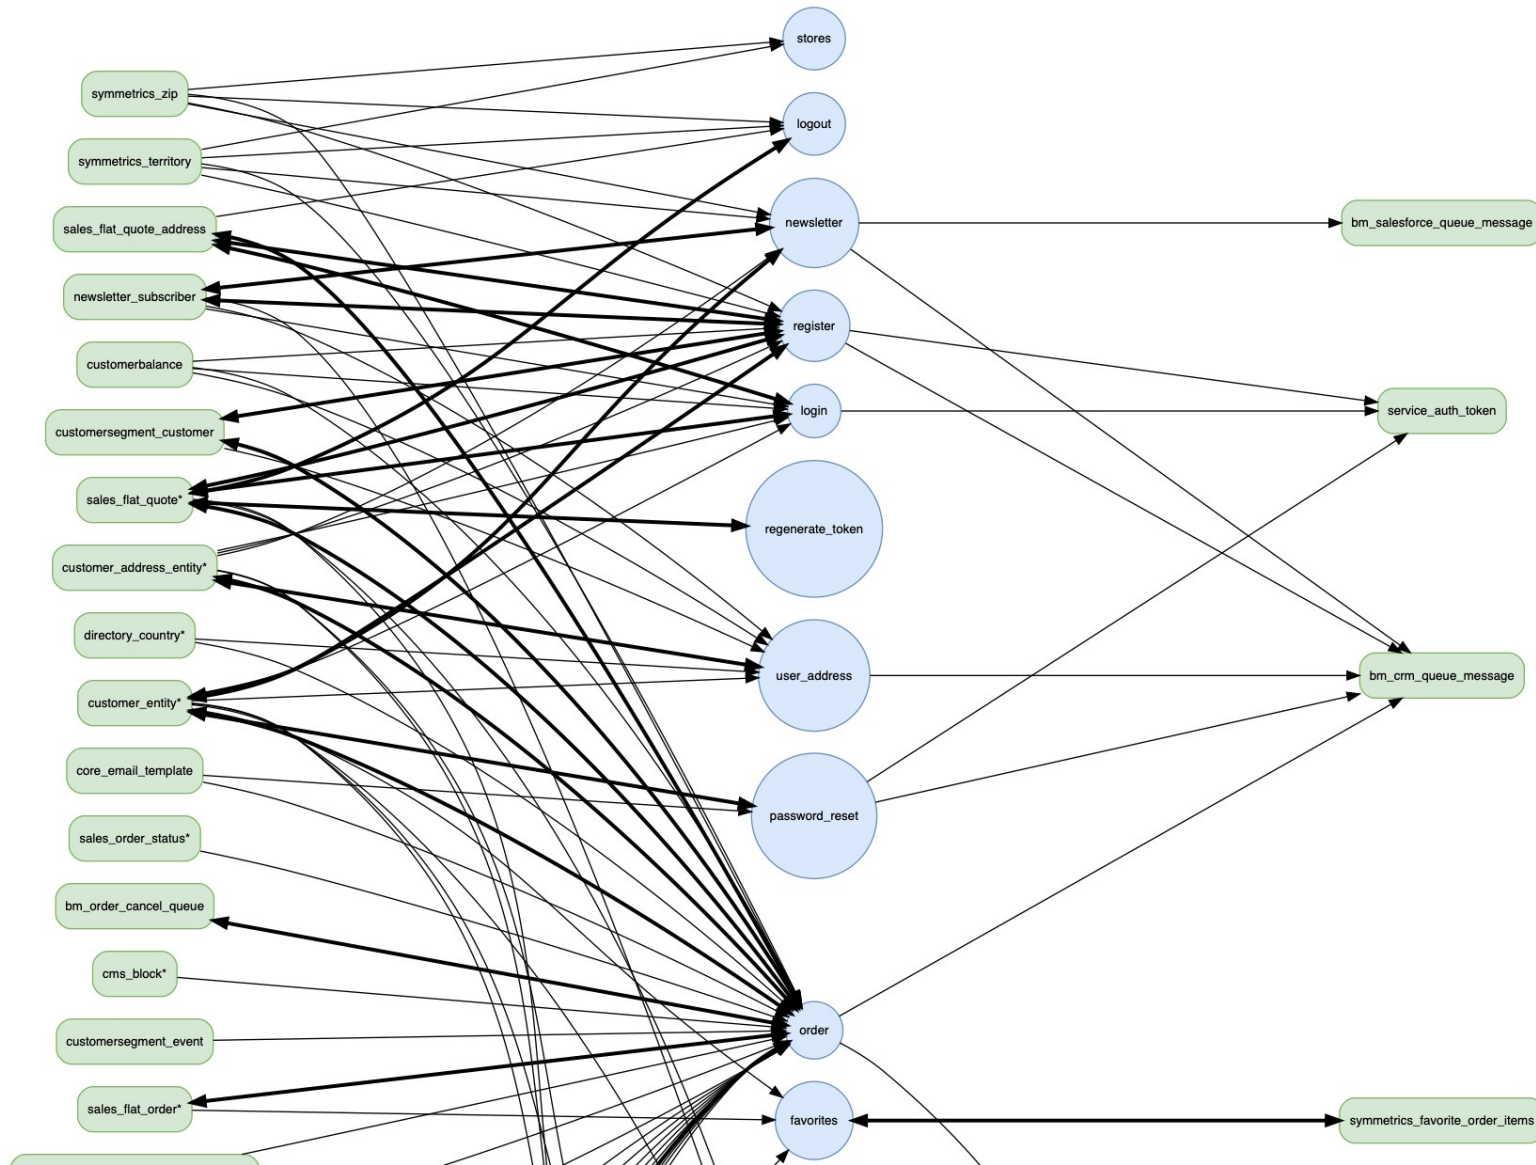

- We decided to stay with PHP and MySQL
most experience, all required libraries and SDKs available, easier to port from PHP to PHP
- Keep existing server infrastructure
- No fullstack framework
→ use our own mini-framework (200 loc)
- Write queries and schema definitions directly in SQL, no ORM, reduce joins by using JSON columns, no foreign keys
- Use JWT instead of sessions
- Single Monorepo for all services, each service with own code base, own database, own composer.json, etc.
- All product data in Algolia
- SOLID, Kiss

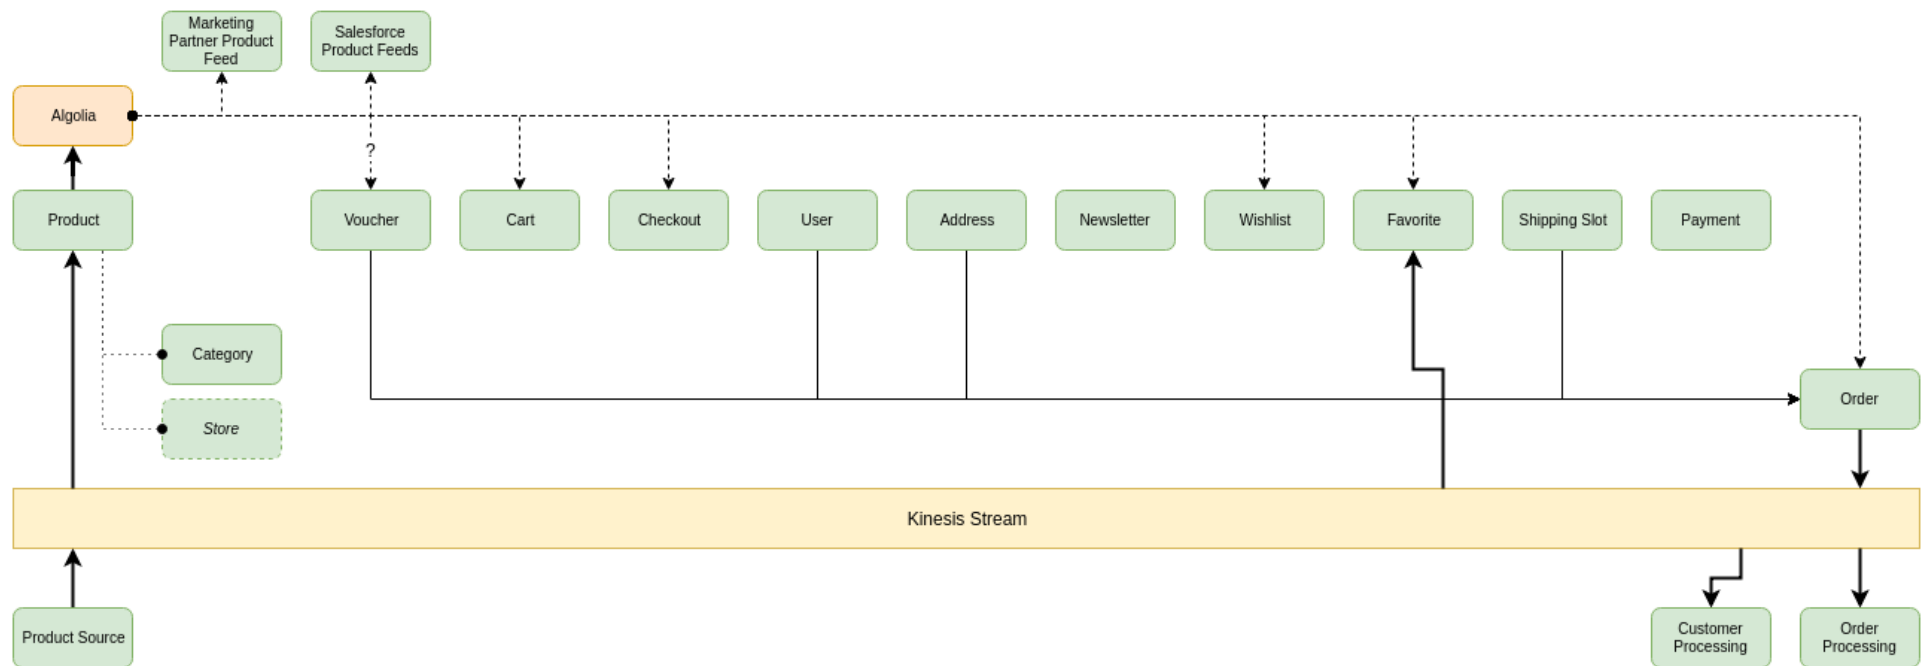

source: www.youtube.com/watch?v=fCt2_AsCWKI

- 100% test coverage, keep Behat tests
- Static code analysis with Psalm
- Enforce coding styles with PHP-CS-Fixer
- new CI/CD with Bitbucket Pipelines

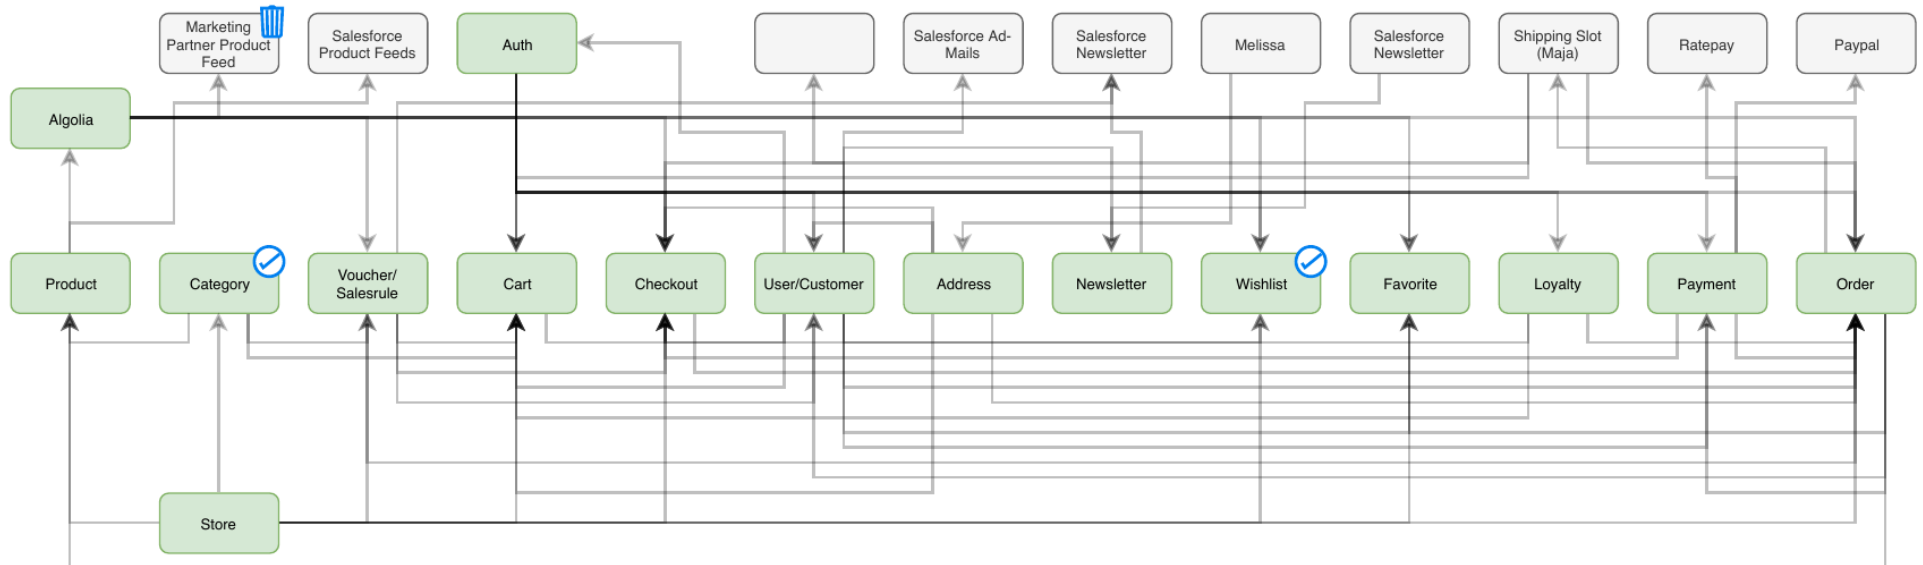

Analyze dependencies on database level

Identify services

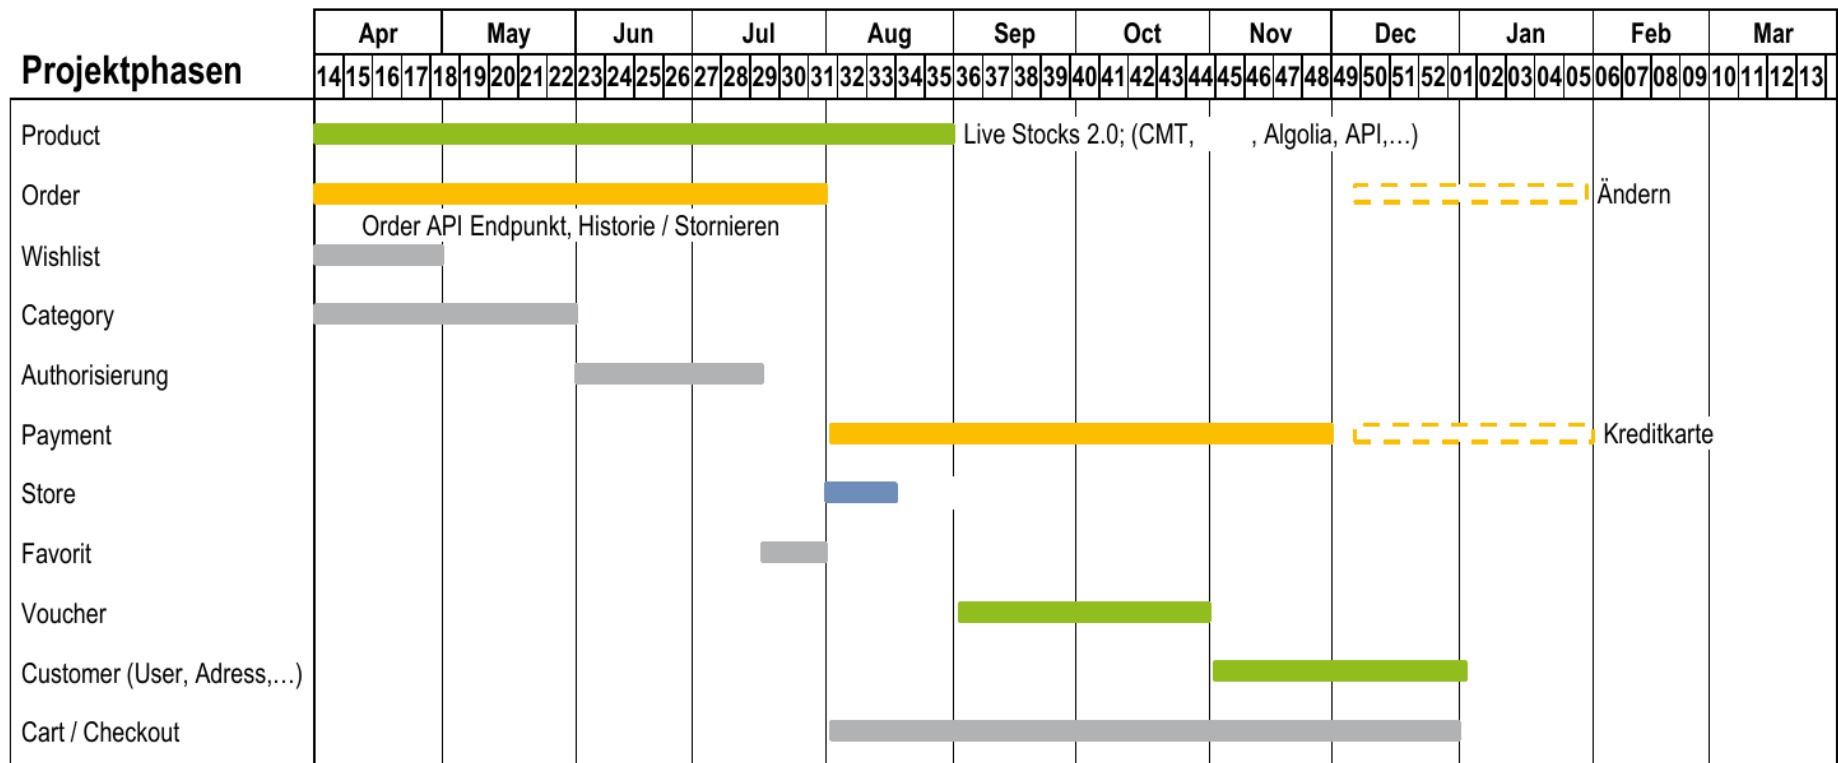

Start with easy services

Implement and launch one by one

Bringmeister.de Partner von 

Build adapters to cut out components with strong dependencies

Before:

After:

Communication between Microservices and external providers

- Synchronous using REST, load balancer (strong consistency)
 - Customer master data, addresses
 - Cart, Vouchers
 - Product data
 - Payment providers
- Synchronous using SOAP (strong consistency)
 - Legacy systems (tour planning)
- Asynchronous using Events (Kinesis)
 - Orders, Logging
- Asynchronous using REST and queues
 - external providers (CRM, Customer Support systems, etc.)
- Forward customer's JWT token between services

Data migration (EAV → JSON)

Using SQL to copy data from old schema to new schema:

```
INSERT INTO customers.customer (email, attributes, created)
SELECT * FROM magento.customer_entity
LEFT JOIN magento.customer_entity_varchar as firstname on
    firstname.entity_id = customer_entity.entity_id and firstname.attribute_id = 5
LEFT JOIN magento.customer_entity_varchar as lastname on
    lastname.entity_id = customer_entity.entity_id and lastname.attribute_id = 7
LEFT JOIN magento.customer_entity_datetime as birthdate on
    birthdate.entity_id = customer_entity.entity_id and birthdate.attribute_id = 11
SET email = customer_entity.email,
    attributes = json_object(
        'first', firstname.value,
        'last', lastname.value,
        'birth', date(birthdate.value),
        'orders', (select count(*) from magento.sales_flat_order
                    where customer_id = customer_entity.entity_id)
    ),
    created = customer_entity.created_at;
```

Data anonymization

Using a separate database and views to provide anonymized production data:

```
SELECT * FROM customers.customer WHERE id = 1234;
```

id: 1234

email: foo.bar@baz.com

attributes: {"first": "Thomas", "last": "Bley", "birth": "1930-02-01", "orders": 42 }

created: 2021-05-06 12:41:11

```
CREATE or REPLACE VIEW customers_anonymized.customer AS
```

```
SELECT id,
```

```
    concat('invalid_', id, '@bringmeister.de') AS email,           # invalid_1234@bringmeister.de
```

```
    json_object(
```

```
        'first', concat('first_', id), 'last', concat('last_', id),      # first_1234, last_1234
```

```
        'birth', '1980-01-02', 'orders', attributes->>"$.orders"        # 1980-01-02, 42
```

```
    ) AS attributes,
```

```
    created
```

```
FROM customers.customer;
```

Results

- Project finished **in time and in quality** (Mar - Nov 2019)
- 10 microservices, 3 admin interfaces
- 99.99% test coverage with unit and integration tests
- Code size reduced to **100 kloc** (coming from 1.8 mloc)
- Data size in database reduced by 80%
- System performance and revenue significantly increased
- Hardware costs reduced by 50%
- External security audit passed
- Tests, Build and Deployment in < 10 minutes
- Development of new features and maintenance much quicker and easier

Developers happy, Management happy, Customers happy with the shop

Implement microservices like a monolith?

source: twitter.com/ddprtt/status/1425418538257428488

Learnings

- Smaller is better
- Don't ignore or delay problems
- Requirements
- Documentation
- Rewriting is a lot of work, but it's worth to do it
- Management support is important
- Monitoring (esp. external service providers, we use Datadog)
- Testing, testing, testing (PHPUnit, Psalm, Trivy, manual, etc.)
- Performance, performance, performance (build a 10x system)

Thanks for listening!
